

# Type-theoretic “general corecursion”

Tarmo Uustalu, Institute of Cybernetics, Tallinn

TYPES, Warsaw, 12–17 October 2010

# When does a structured recursion diagram define a function?

We are interested defining (= definitely describing) a function  $f : A \rightarrow B$  by an equation of the form:

$$\begin{array}{ccc} FA & \xleftarrow{\alpha} & A \\ Ff \downarrow & & \downarrow f \\ FB & \xrightarrow{\beta} & B \end{array}$$

$F$  – branching type of recursive call [corecursive return] trees (an endofunctor)

$\alpha$  – marshals arguments for recursive calls (an  $F$ -coalgebra)

$\beta$  – collects recursive call results (an  $F$ -algebra)

## Some good cases (1): Initial algebra

$$\begin{array}{ccc} 1 + \text{El} \times \text{List} & \xleftarrow{[\text{nil}, \text{cons}]^{-1}} & \text{List} \\ \downarrow 1 + \text{El} \times f & & \downarrow f \\ 1 + \text{El} \times B & \xrightarrow{\beta} & B \end{array}$$

E.g., for  $B = \text{List}$ ,  $\beta = \text{ins}$ , we get  $f = \text{isort}$ .

A unique  $f$  exists for any  $(B, \beta)$  because  $(\text{List}, [\text{nil}, \text{cons}])$  is the *initial algebra* of  $1 + \text{El} \times (-)$ .

$f$  is the fold of  $(B, \beta)$ .

## Some good cases (2): Recursive coalgebras

$$\begin{array}{ccc} 1 + \text{List} \times \text{El} \times \text{List} & \xleftarrow{\text{qsplit}} & \text{List} \\ \downarrow 1+f \times \text{El} \times f & & \downarrow f \\ 1 + B \times \text{El} \times B & \xrightarrow{\beta} & B \end{array}$$

$\text{qsplit nil} = \text{inl } *$ ;  $\text{qsplit (cons (x, xs))} = \text{inr (xs|}_{\leq x}, x, \text{xs|}_{> x})$

E.g., for  $B = \text{List}$ ,  $\beta = \text{app} \circ (\text{List} \times \text{cons})$ , we get  $f = \text{qsort}$ .

$(\text{List}, \text{qsplit})$  is not the inverse of the initial algebra of  $1 + (-) \times \text{El} \times (-)$ , but we still have a unique  $f$  for any  $(B, \beta)$ .

We say that  $(\text{List}, \text{qsplit})$  is a *recursive coalgebra* of  $1 + (-) \times \text{El} \times (-)$ .

[The inverse of the initial  $F$ -algebra is the final recursive  $F$ -coalgebra.]

## Some good cases (3): Final coalgebra

$$\begin{array}{ccc} \text{El} \times A & \xleftarrow{\alpha} & A \\ \downarrow 1 + \text{El} \times f & & \downarrow f \\ \text{El} \times \text{Str} & \xrightarrow{\langle \text{hd}, \text{tl} \rangle^{-1}} & \text{Str} \end{array}$$

E.g., for  $A = \text{Str}$ ,  $\alpha = \langle \text{hd}, \text{tl} \circ \text{tl} \rangle$ , we get  $f = \text{dropeven}$ .

A unique  $f$  exists for any  $(A, \alpha)$  because  $(\text{Str}, \langle \text{hd}, \text{tl} \rangle)$  is the *final coalgebra* of  $\text{El} \times (-)$ .

$f$  is the *unfold* of  $(A, \alpha)$ .

## Some good cases (4): Corecursive algebras

$$\begin{array}{ccc} A \times \text{El} \times A & \xleftarrow{\alpha} & A \\ f \times \text{El} \times f \downarrow & & \downarrow f \\ \text{Str} \times \text{El} \times \text{Str} & \xrightarrow{\text{smerge}} & \text{Str} \end{array}$$

$$\text{hd}(\text{smerge}(xs_0, x, xs_1)) = x$$

$$\text{tl}(\text{smerge}(xs_0, x, xs_1)) = \text{smerge}(xs_1, \text{hd } xs_0, \text{tl } xs_1)$$

$(\text{Str}, \text{smerge})$  is not the inverse of the final coalgebra of  $(-) \times \text{El} \times (-)$ , but a unique  $f$  still exists for any  $(A, \alpha)$ .

We say that  $(\text{Str}, \text{smerge})$  is a *corecursive algebra* of  $(-) \times \text{El} \times (-)$ .

[The inverse of the final  $F$ -coalgebra is the initial corecursive  $F$ -algebra.]

# General case (1): Inductive domain predicate

Bove-Capretta

For given  $(A, \alpha)$ , define a predicate  $\text{dom}$  on  $A$  **inductively** by

$$\frac{a : A \quad (\tilde{F} \text{ dom}) (\alpha a)}{\text{dom } a}$$

For any  $(B, \beta)$ , there is  $f : A|_{\text{dom}} \rightarrow B$  uniquely solving

$$\begin{array}{ccc} F(A|_{\text{dom}}) & \xleftarrow{\alpha|_{\text{dom}}} & A|_{\text{dom}} \\ Ff \downarrow & & \downarrow f \\ FB & \xrightarrow{\beta} & B \end{array}$$

If  $\forall a : A. \text{dom } a$ , which is the same as  $A|_{\text{dom}} \cong A$ , then  $f$  is a unique solution of the original equation.

## General case (1): Inductive domain predicate ctd

For  $A = \text{List}$ ,  $\alpha = \text{qsplit}$ ,  $\text{dom}$  is defined inductively by

$$\frac{}{\text{dom nil}} \quad \frac{x : \text{El} \quad xs : \text{List} \quad \text{dom}(xs|_{\leq x}) \quad \text{dom}(xs|_{> x})}{\text{dom}(\text{cons}(x, xs))}$$

We can prove that  $\forall xs : \text{List}. \text{dom } xs$ .

Hence  $(\text{List}, \text{qsplit})$  is recursive.

## Wellfounded induction

If  $A|_{\text{dom}} \cong A$ , the coalgebra  $(A, \alpha)$  is said to be *wellfounded*.

Wellfoundedness gives an induction principle on  $A$ : For any predicate  $P$  on  $A$ , we have

$$\frac{a : A \quad \begin{array}{c} a' : A \quad (\tilde{F} P)(\alpha a') \\ \vdots \\ P a \end{array}}{P a}$$

We have seen that wellfoundedness suffices for recursiveness. In fact, it is also necessary.

## Wellfounded induction ctd

For  $A = \text{List}$ ,  $\alpha = \text{qsplit}$ , we get this induction principle:

$$\frac{\begin{array}{c} x : \text{El} \quad xs' : \text{List} \quad P(xs' |_{\leq x}) \quad P(xs' |_{> x}) \\ \vdots \\ P(\text{cons}(x, xs')) \end{array}}{xs : \text{List} \quad P \text{ nil}} \quad P \text{ xs}$$

## General case (2): Inductive graph relation

Bove

For given  $(A, \alpha)$ ,  $(B, \beta)$ , define a relation  $\downarrow$  between  $A$ ,  $B$  inductively by

$$\frac{a : A \quad bs : FB \quad (\alpha a) (\tilde{F} \downarrow) bs}{a \downarrow (\beta bs)}$$

Further, define a predicate  $\text{Dom}$  on  $A$  by

$$\text{Dom } a = \exists b : B. a \downarrow b$$

It is easy that  $\forall a : A, b, b' : B. a \downarrow b \wedge a \downarrow b' \rightarrow b = b'$ .

Moreover,  $\forall a : A. \text{Dom } a \leftrightarrow \text{dom } a$ .

So,  $\text{Dom}$  does not really depend on the given  $(B, \beta)$ !

## General case (2): Inductive graph relation ctd

We know that there is  $f : A|_{\text{Dom}} \rightarrow B$  uniquely solving

$$\begin{array}{ccc} F(A|_{\text{Dom}}) & \xleftarrow{\alpha|_{\text{Dom}}} & A|_{\text{Dom}} \\ Ff \downarrow & & \downarrow f \\ FB & \xrightarrow{\beta} & B \end{array}$$

And, if  $\forall a : A. \text{Dom } a$ , which is the same as  $A|_{\text{Dom}} \cong A$ , then  $f$  is a unique solution of the original equation.

As a matter of fact, recursiveness and wellfoundedness are equivalent exactly because  $\forall a : A. \text{Dom } a \leftrightarrow \text{dom } a$ .

## General case (2): Inductive graph relation ctd

For  $A = \text{List}$ ,  $\alpha = \text{qsplit}$ ,  $B = \text{List}$ ,  $\beta = \text{app} \circ (\text{List} \times \text{cons})$ , the relation  $\downarrow$  is defined inductively by

$$\frac{}{\text{nil} \downarrow \text{nil}} \quad \frac{x : \text{El} \quad xs : \text{List} \quad xs|_{\leq x} \downarrow ys_0 \quad xs|_{> x} \downarrow ys_1}{\text{cons}(x, xs) \downarrow \text{app}(ys_0, \text{cons}(x, ys_1))}$$

# Trouble: Inductive domain/graph don't work for corecursion

Unfortunately, for our dropeven example,

$$\begin{array}{ccc} \text{El} \times \text{Str} & \xleftarrow{\langle \text{hd}, \text{tl} \circ \text{tl} \rangle} & \text{Str} \\ \downarrow 1 + \text{El} \times \text{dropeven} & & \downarrow \text{dropeven} \\ \text{El} \times \text{Str} & \xrightarrow{\langle \text{hd}, \text{tl} \rangle^{-1}} & \text{Str} \end{array}$$

we get  $\text{dom} \cong 0!$

Now, surely there is a unique function from  $0 \rightarrow \text{Str}$ . But this is uninteresting!

???

# General case (3): Coinductive bisimilarity relation

Capretta, Uustalu, Vene

For given  $(B, \beta)$ , define a relation  $\approx$  on  $B$  **coinductively** by

$$\frac{bs, bs' : FB \quad \beta bs \approx \beta bs'}{bs (\tilde{F} \approx^*) bs'}$$

If  $\forall b, b' : B. b \approx b' \rightarrow b = b'$ , which is the same as  $B/\approx^* \cong B$ , we say that  $(B, \beta)$  is *antifounded*.

This does not suffice for existence of  $f$  satisfying

$$\begin{array}{ccc} FA & \xleftarrow{\alpha} & A \\ Ff \downarrow & & \downarrow f \\ F(B/\approx^*) & \xrightarrow{\beta/\approx^*} & B/\approx^* \end{array}$$

but it suffices for uniqueness!

## General case (3): Coinductive bisimilarity relation

For  $B = \text{Str}$ ,  $\beta = \text{qmerge}$ , the relation  $\approx$  is defined coinductively by

$$\frac{\begin{array}{l} xs_0, xs_1 : \text{Str}, \\ x, x' : \text{El}, xs'_0, xs'_1 : \text{Str} \end{array} \quad \begin{array}{l} \text{smerge}(xs_0, x, xs_1) \\ \approx \text{smerge}(xs'_0, x', xs'_1) \end{array}}{xs_0 \approx^* xs'_0 \wedge x = x' \wedge xs_1 \approx^* xs'_1}$$

It turns out that  $\forall xs, xs' : \text{Str}. xs \approx xs' \rightarrow xs = xs'$ .

Based on this knowledge, we know that solutions are unique, but need not exist.

# Antifounded coinduction

We saw that antifoundedness of  $(B, \beta)$  does not suffice for corecursion from  $A$  to  $B$  for any  $(A, \alpha)$ .

The converse also fails: not every corecursive algebra  $(B, \beta)$  is antifounded.

However, for an antifounded algebra  $(B, \beta)$ , we do get an interesting coinduction principle on  $B$ : For any relation  $R$  on  $B$ , we have

$$\frac{b, b' : B \quad b R b' \quad \begin{array}{c} bs, bs' : FB \quad (\beta bs) R (\beta bs') \\ \vdots \\ bs (\tilde{F} R^*) bs' \end{array}}{b = b'}$$

# Antifounded coinduction ctd

For  $B = \text{Str}$ ,  $\beta = \text{qmerge}$ , we get this coinduction principle:

$$\frac{\begin{array}{l} xs_0, xs_1 : \text{Str}, \\ x, x' : \text{El}, xs'_0, xs'_1 : \text{Str} \end{array} \quad \begin{array}{l} \text{smerge}(xs_0, x, xs_1) \\ R \text{smerge}(xs'_0, x', xs'_1) \\ \vdots \end{array}}{xs, xs' : \text{Str} \quad xs R xs' \quad xs_0 R^* xs'_0 \wedge x = x' \wedge xs_1 R^* xs'_1} \quad xs = xs'$$

## General case (4): Coinductive graph relation

For given  $(A, \alpha)$ ,  $(B, \beta)$ , define a relation  $\downarrow^\infty$  between  $A$ ,  $B$  **coinductively** by

$$\frac{a : A \quad bs : FB \quad a \downarrow^\infty (\beta bs)}{(\alpha a) (\tilde{F} \downarrow^\infty) bs}$$

Define a predicate  $\text{Dom}^\infty$  on  $A$  by

$$\text{Dom}^\infty a = \exists b : B. a \downarrow^\infty b$$

and a relation  $\equiv$  on  $B$  by

$$b \equiv b' = \exists a : A. a \downarrow^\infty b \wedge a \downarrow^\infty b'$$

## General case (4): Coinductive graph relation ctd

Now we have  $f : A|_{\text{Dom}^\infty} \rightarrow B/\equiv^*$  uniquely solving

$$\begin{array}{ccc} F(A|_{\text{Dom}^\infty}) & \xleftarrow{\alpha|_{\text{Dom}^\infty}} & A|_{\text{Dom}^\infty} \\ Ff \downarrow & & \downarrow f \\ F(B/\equiv^*) & \xrightarrow{\beta/\equiv^*} & B/\equiv^* \end{array}$$

If both  $\forall a : A. \text{Dom}^\infty a$  and  $\forall b, b' : B. b \equiv b' \rightarrow b = b'$ , which are the same as  $A|_{\text{Dom}^\infty} \cong A$  resp.  $B/\equiv^* \cong B$ , then  $f$  uniquely solves the original equation.

Notice, however, that we get a unique solution only for our given  $(A, \alpha)$ : We have not obtained that  $(B, \beta)$  is corecursive.

## General case (4): Coinductive graph relation ctd

For  $B = \text{Str}$ ,  $\beta = \text{smerge}$  and any fixed  $A$ ,  $\alpha$ , the relation  $\downarrow^\infty$  is defined coinductively by

$$\frac{a : A \quad xs_0 : \text{Str}, x : \text{El}, xs_1 : \text{Str} \quad a \downarrow^\infty \text{smerge}(xs_0, x, xs_1)}{\text{fst } a \downarrow^\infty xs_0 \wedge \text{fst}(\text{snd } a) = x \wedge \text{snd}(\text{snd } a) \downarrow^\infty xs_1}$$

It turns out that  $\forall a : A. \text{Dom}^\infty a$  and

$\forall xs, xs' : \text{Str}. xs \equiv xs' \rightarrow xs = xs'$  no matter what  $A$ ,  $\alpha$  are.

So in this case we do have a unique solution  $f$  for any  $A$ ,  $\alpha$ , i.e.,  $(\text{Str}, \text{smerge})$  is corecursive.

# Conclusion

There are two kinds of partiality: some arguments may be not in the domain, some values not crisp.

Bove-Capretta method extends to recursive equations where unique solvability is not due to termination, but productivity or a combination.

Instead of one condition to check by ad-hoc means, there are two in the general case.

The theory of corecursion/coinduction is not as simple and clean as that of recursion/induction — admitting coinduction is different from admitting corecursion.
